NUEN 647 Final Project

Uncertainty quantification of depletion calculations for specific isotopes using ORIGEN2.

I Introduction

Determing composition of irradiated fuel is of importance for a myriad of reasons. Whether for flux calculations, reprocessing, or irradiation history verification, calculating fuel composition requires a Bateman solver, and a means for building a sparse matrix.

Applications using these compositions rarely report the uncertainty associated with results, even when inputs, such as flux shape, fission yield, cross sections, and half-lives have varying degrees of uncertainty. Further sources of error in this calculation are due to the multi-group approximation, and single point approximation, but will not be explored here.

Several isotope concentrations, shown in Table 1, were calculated as a function of burnup with the depletion code ORIGEN2 for a PWR system with 3 Wt% enriched uranium. ORIGEN2 solves the bateman equations with the matrix expoential method and requires a library with decay and cross section information. Cross sections and fission product yields are reduced to single group through flux averaging before execution of the code, with the assumption that the flux has the same shape as a typical PWR.

The uncertainty of concentrations were determined by varying the cross section, fission yield, and half-life information that was fed into ORIGEN2. The uncertainties on cross sections were determined by calculating the range of the single group cross section, taking the mid point as a mean, the range as a standard deviation, and assuming a Gaussian distribution. A similar calculation was done for the fisison yields, and half-life distributions were taken at face value as normally distributed.

Table 1: Isotope solve list.

$^{133}\mathrm{Cs}$	136 Ba	$^{153}\mathrm{Eu}$
$^{134}\mathrm{Cs}$	138 Ba	$^{154}\mathrm{Eu}$
$^{135}\mathrm{Cs}$	$^{149}\mathrm{Sm}$	$^{239}\mathrm{Pu}$
$^{137}\mathrm{Cs}$	$^{150}\mathrm{Sm}$	$^{242}\mathrm{Pu}$
$^{148}\mathrm{Nd}$	$^{106}\mathrm{Rh}$	$^{125}\mathrm{Sb}$

II Objectives

☑ Build ORIGEN2 model for thermal system which calculates concentrations of isotopes shown in Table 1.

The model irradiates 1 metric ton of US PWR fuel for a single cycle (15,000 MWd/Mt). The calculations use a constant power assumption of 37.5 W/g. The model does not include the oxygen because we are not interested in the activation of oxygen. Cross section modification throughout the calculation use the changing flux associated with a US PWR.

Initial verification of the model analyzed the end concentration of 137 Cs and calculated the burn-up from that value. This calculation does not have an exact value for the yield of 137 Cs and is used qualitatively as a sanity check.

$$\frac{552.8 \text{ g}^{137}\text{Cs}}{Mt} \cdot \frac{6.022E23 \text{ atoms}}{137 \text{ g}^{137}\text{Cs}} \cdot \frac{\text{Fission}}{0.06 \text{ atoms}} \cdot \frac{200 \text{ MeV}}{\text{Fission}} \cdot \frac{1.602E - 19 \text{ MJ}}{1 \text{ MeV}} \cdot \frac{1 \text{ day}}{86400 \text{ s}} = 15,018 \frac{\text{MWd}}{Mt} \cdot \frac{1.002E - 19 \text{ MJ}}{1 \text{ MeV}} \cdot \frac{1 \text{ day}}{1 \text{ day}} = 15,018 \frac{\text{MWd}}{1 \text{ MeV}} \cdot \frac{1.002E - 19 \text{ MJ}}{1 \text{ day}} \cdot \frac{1.002E - 19 \text{ MJ}}{1 \text{ day}} = 15,018 \frac{\text{MWd}}{1 \text{ day}} = 15,018 \frac$$

ORIGEN2 reads in cross section information through a file named "TAPE9.inp", specified by the 8th input on the LIB card. "TAPE9.inp" needs at least 3 cross section libraries. These are specified by the 5th 6th and 7th inputs on the LIB card as 601, 602, and 603 for the activation products, actinides, and fission products, respectively. The input for ¹³⁷Cs from library 603 is shown in the listing below, with a corresponding key shown in Table 2 [1].

Listing 2: ¹³⁷Cs cross section library 603 input

603	551370 2.546E-02 0.0	0.0	0.0	0.0	0.0	1.0
603	1.81E-02 $6.78E-01$	1.25E-01 2.08E	-01 7.56E-	01 9.45E-02	9.43E - 02	9.43E-02

Table 2: Key to parameters in cross section library

LIB	NUCLID	(n,γ)	(n,2n)	(n,α)	(n,p)	(n,γ^*)	$(n,2n^*)$	YYN
LIB	$Y(^{232}Th)$	$Y(^{233}U)$	$Y(^{235}U)$	$Y(^{238}U)$	$Y(^{239}Pu)$	$Y(^{241}Pu)$	$Y(^{245}Cm)$	$Y(^{249}Cf)$

The cross section, σ_{γ} will be modified based on the locations in the cross section libraries shown above. Half-life information is contained in the decay libraries 1, 2, and 3 for activation products, actinides, and fission products, respectively. These values will not be modified to reduce the scope of the project.

A program was writen to modify σ_{γ} , yield, or half-life based on lines from a text file. This code is shown below but will only be used to modify cross section.

  print("--- %s seconds ---" % (time.time() - start time))
```

□ Determine variance of Cross-sections

In order to determine the sigma variables I am planning on flux averaging via:

$$\sigma = \frac{\int \sigma(E)\phi(E)dE}{\int \phi(E)dE}$$

where:

$$\phi(E) = C_1 \cdot \frac{E}{E_0^2} \cdot exp\left(-\frac{E}{E_0}\right) \qquad E < E_{max,th}$$

$$= \frac{C_2}{E} \qquad E_{max,th} < E < E_{max,epi}$$

$$= C_3 \cdot \frac{\sqrt{\frac{E}{E_f}}}{E_f} \cdot exp\left(-\frac{E}{E_f}\right) \qquad E > E_{max,epi}$$

and:

$$C_1 = \frac{E_0^2}{E_{max,th}^2} e^{E_{max,th}/E_0}$$

$$C_2 = 1$$

$$C_3 = \frac{E_f}{E_{max,epi}} \cdot e^{\frac{E_{max,epi}}{E_f}} \frac{1}{\sqrt{\frac{E_{max,epi}}{E_f}}}$$

Where: $E_{max,th} = 0.50 \,\mathrm{eV}$, $E_{max,epi} = 1E5 \,\mathrm{eV}$, $\theta_{th} = 0.09 \,\mathrm{eV}$ (1045 K), and $\theta_{fis} = 1.35E6 \,\mathrm{eV}$. These values were picked because they minimized the difference between the cross-sections in the TAPE9 file, and those calculated with ENDF-VII and the above method. This is highlighted in figure 1. Half of this error is from $^{238}\mathrm{U}$.

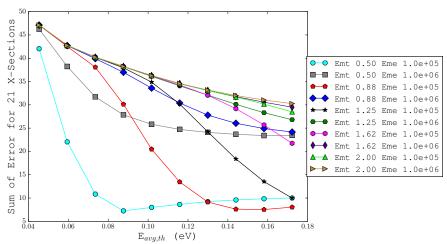

Figure 1: Minimized error for 21 cross section calculations

The flux spectrum is shown as below:

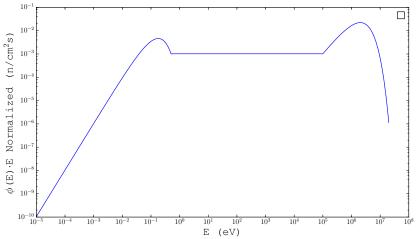

Figure 2: Flux Spectra used for weighting x-sections and yields

I was going to calculate σ_{γ} with nominal cross section values, then with error subtracted, and then added. These values would constitue a mean with error. A similar calculation would be done for the yields.

☐ Create a sampling space for all possible variations of calculations

I might have to reduce the number of elements to look at, maybe I'll start by just looking at 154 Eu.

$$^{153}Pm \xrightarrow{\beta^-} ^{153}Sm \xrightarrow{\beta^-} ^{153}Eu \xrightarrow{(n,\gamma)} ^{154}Eu$$

Table 3: Summary of parameters to vary for ¹⁵⁴Eu

Isotope	Half-life	σ_{γ}	Yield
$^{-153}\mathrm{Pm}$	$5.25 \pm 0.02 \; \mathrm{min}$	SIGMA	Yield
$^{153}\mathrm{Sm}$	$46.284 \pm 0.004 \text{ hr}$	SIGMA	Yield
$^{153}\mathrm{Eu}$	Stable	SIGMA	Yield
$^{154}\mathrm{Eu}$	$8.60 \pm 0.01 \text{ y}$	SIGMA	Yield

 \Box Determine importance of various uncertain parameters by running the code a number of times randomly sampling the sample space (still not 100% sure how to do this - not even 50% sure how to do this)

III Quantities of Interest and Uncertain Parameters

Quantities of interest are shown in Table 1 above. Uncertain parameters are listed below:

- Fission yield
- Cross sections
- Half-lives

IV Prediction

The first major prediction for this project is that half-lives will not have a large impact on results because they are relatively well known. Secondly, ¹²⁵Sb is notorious for being difficult to calculate correctly, I would would predict that there would be large uncertainties due to uncertainties in the cross section data.
